Angular memory, physical site motion and observation coverage

Completed 32,000-unit ring histories • 12 independent seeds per condition • both fixed input strengths

Angular geometry: Δθ = 2π Δs / C. Equal physical displacement subtends a smaller angle on a larger boundary.
Wave-pinning: high-input physical displacement is smaller at C60 than C20. Holmes: higher angular memory coexists with nonmonotone physical displacement and decreasing single-site coverage. Goryachev requires a forced-state qualification.

Bars: source 95% whole-seed bootstrap intervals. Signed finite-window areas are not fitted or extrapolated persistence times.
Site endpoints must pass the complete local-profile and R ≥ 0.1 gate; continued site identity is unproven. All windows are retained in the companion sheet.
