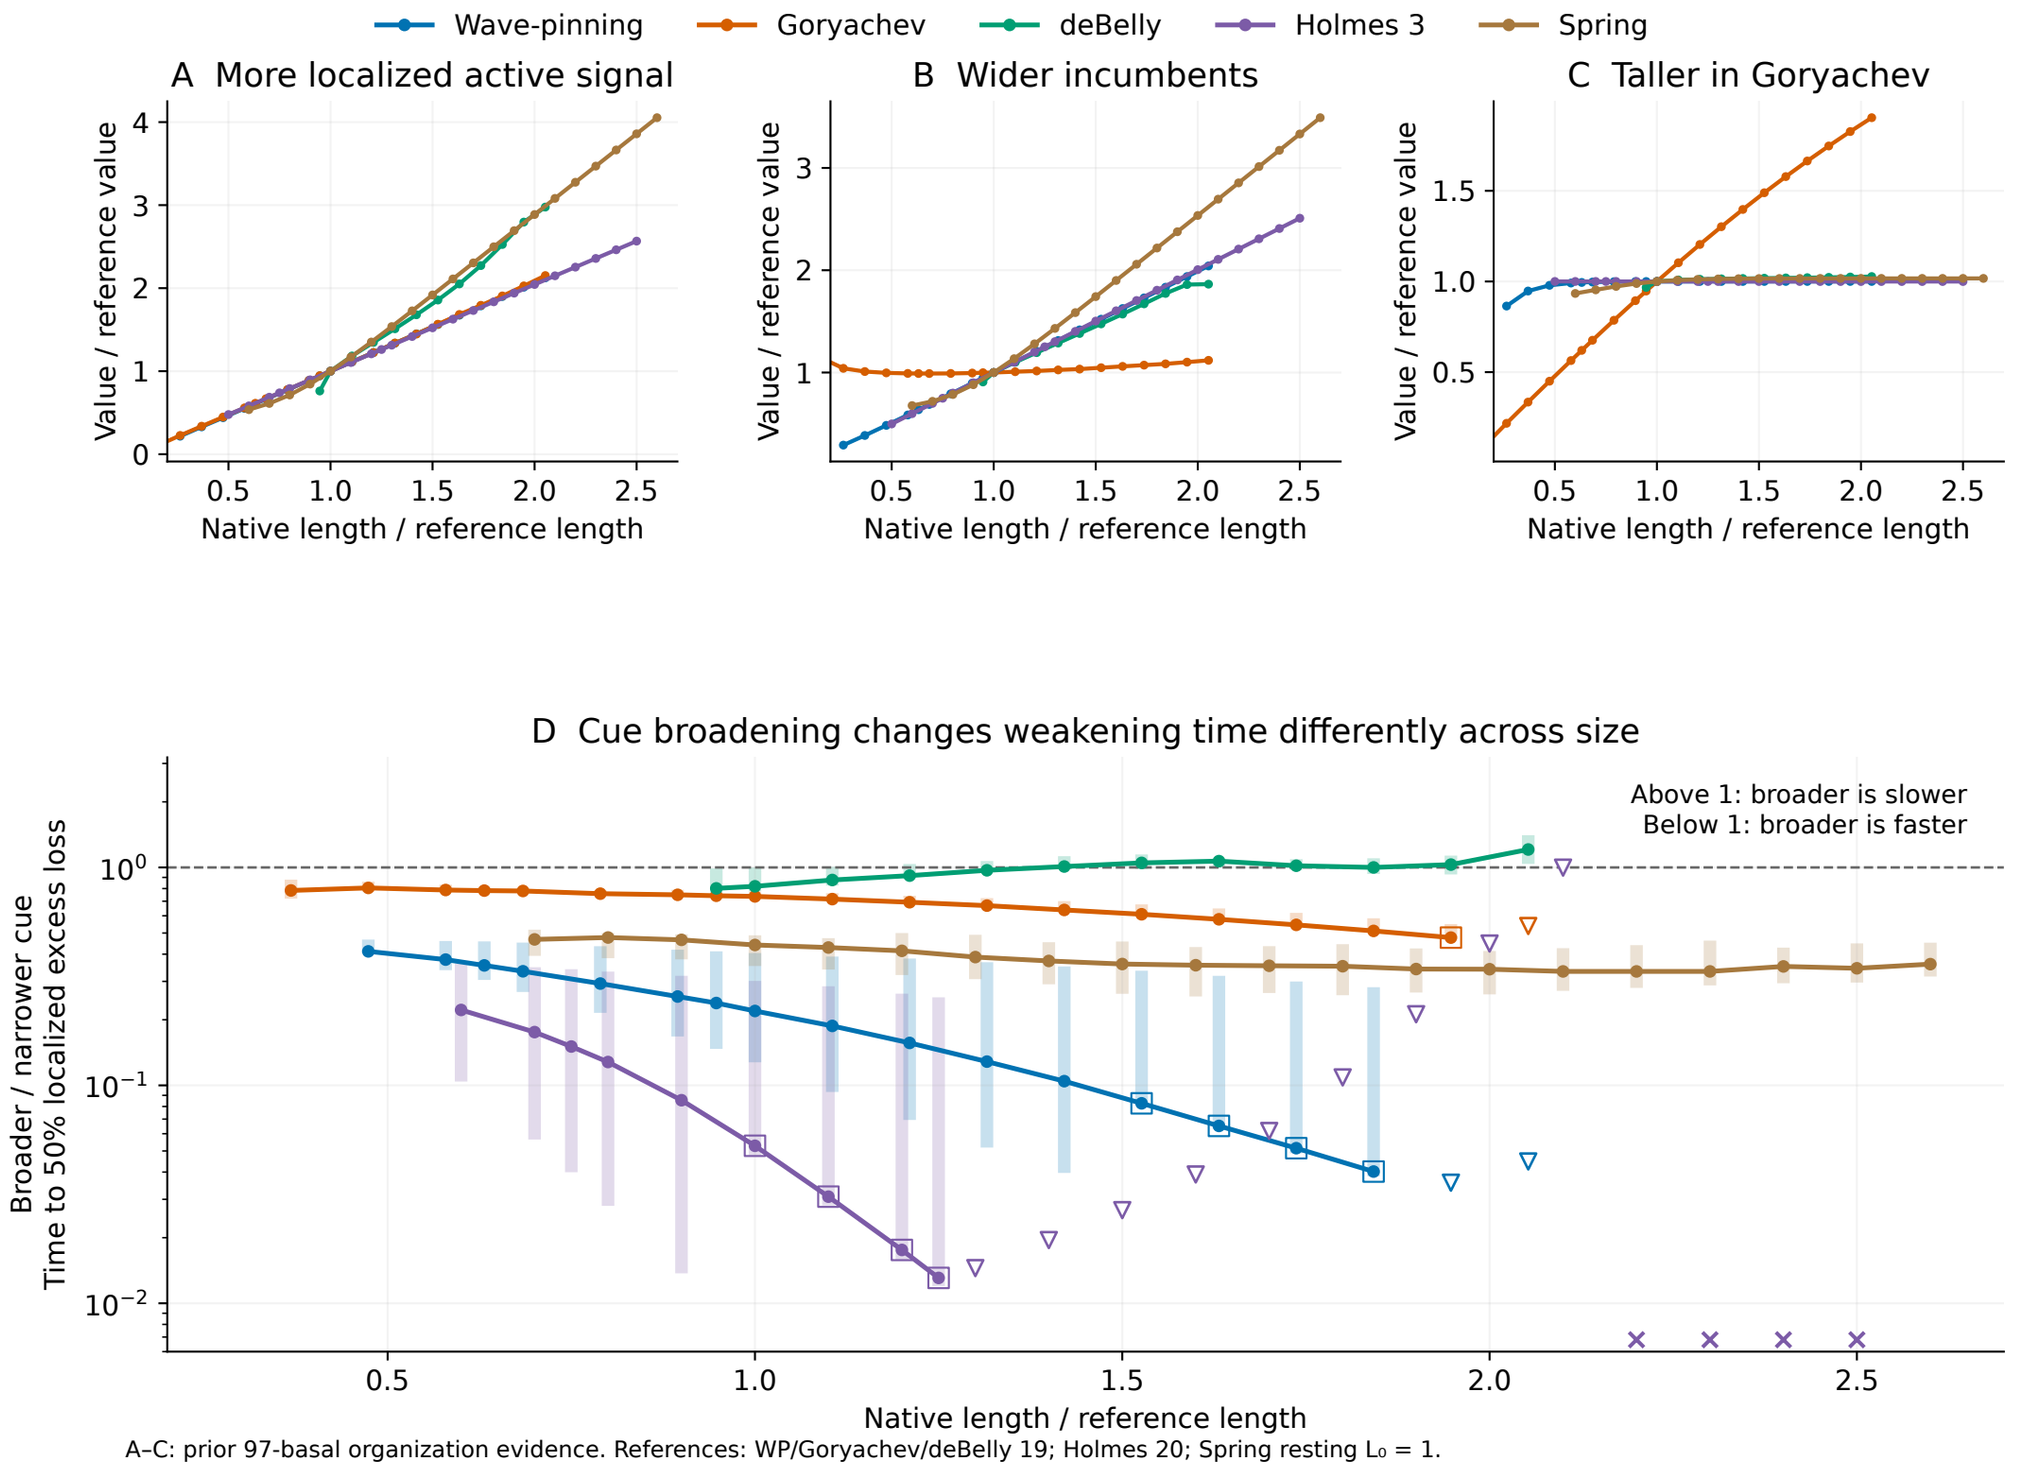
Larger incumbents; length-dependent cue compensation

Provisional main-panel candidate · retained organization plus new full-field experiments



A–C: prior 97-basal organization evidence. References: WP/Goryachev/deBelly 19; Holmes 20; Spring resting $L_0 = 1$.

D: fixed native peak; widths 1.5 → 5 (Spring 0.1 → 0.4). Broader input also increases integrated dose; models are not matched optical actuators.

Pale ranges: observed ratios across 25/50/75% loss, three floors and two cores; sensitivity ranges, not confidence intervals.

Open triangles: finite-window bounds. Hollow squares: incomplete sensitivity. × at axis floor: neither cue has a sampled primary loss entry.
