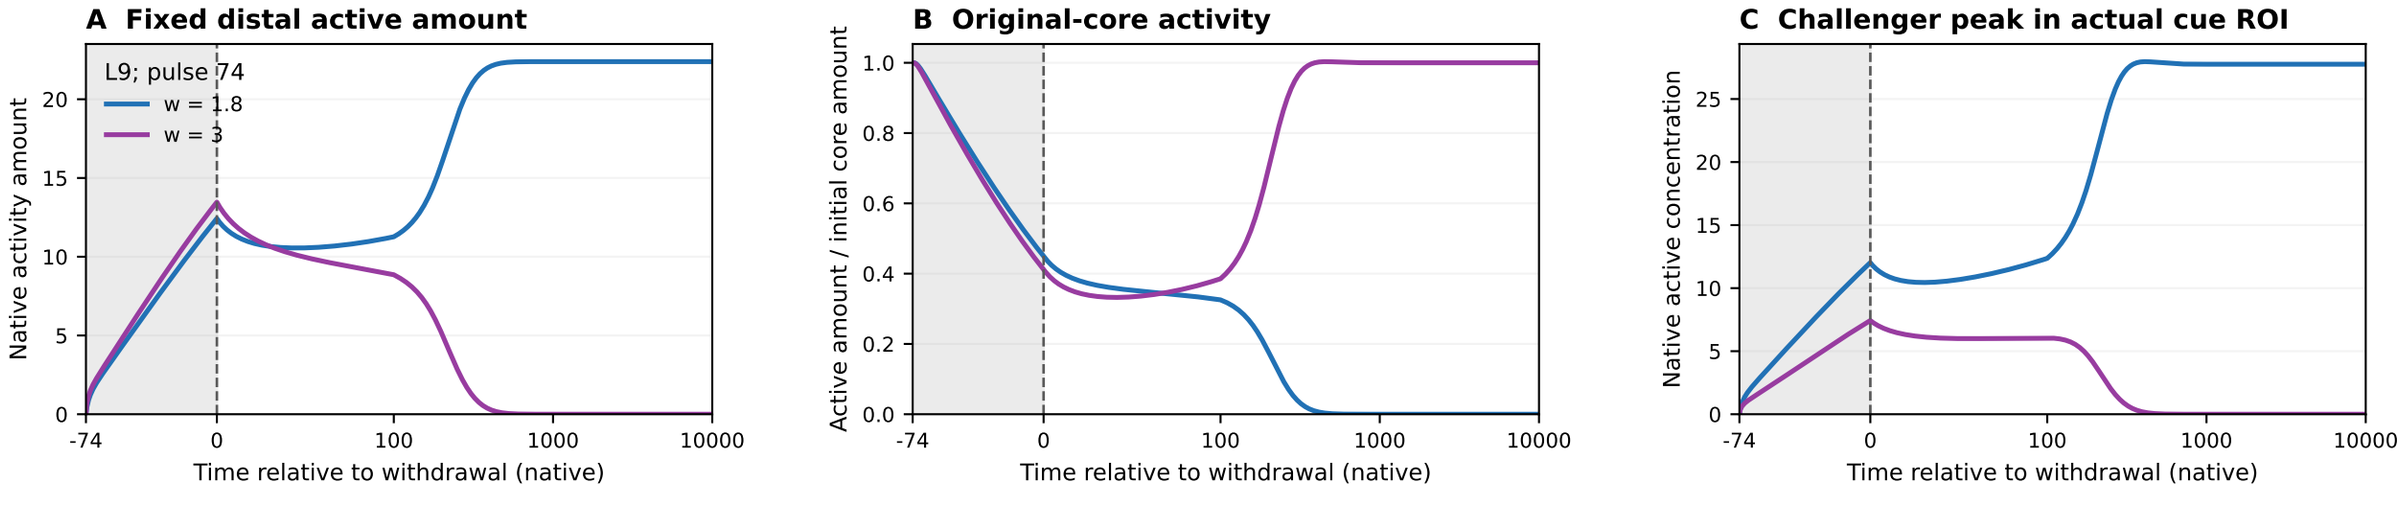
Broader challengers can lose or win after cue withdrawal

Goryachev: exact shared basal and requested peak 6.4 within each pair; the larger cohort receives a longer pulse.

Read the amount, original-region weakening and local concentration together; no single peak or depletion threshold predicts both pairs.



L9: the broader cue leaves more distal material but a lower peak; that response disappears while the original region recovers.

L25: the broader cue also lowers the challenger peak, but now the original region is depleted more and the challenger is retained.

Within-pair basals and peak are identical. The two rows change length, pulse duration and the width interval; they do not isolate a causal length effect.

Grey = cue on. Time axis is linear for $|t| \le 100$ and logarithmic outside. Curves use selected actual saved frames; all native field tails pass.

Distal ROI = whole cells with centres ≥ L/2; each pair uses identical weights. Native N = 201; input × inactive, dose and clock are not optically calibrated.
