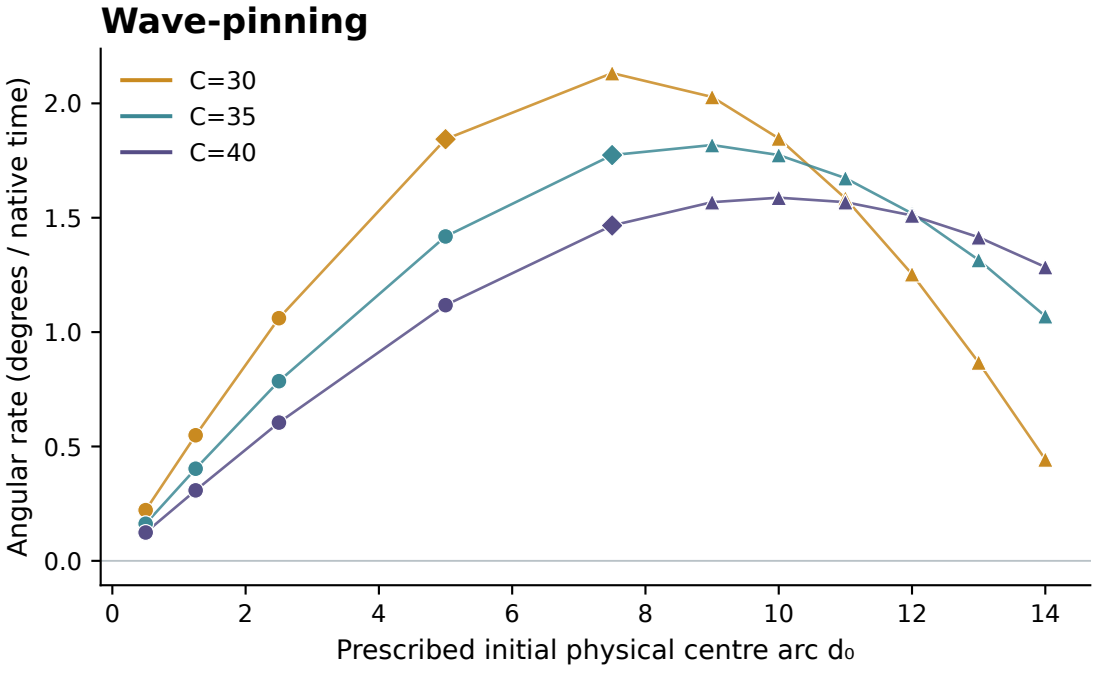
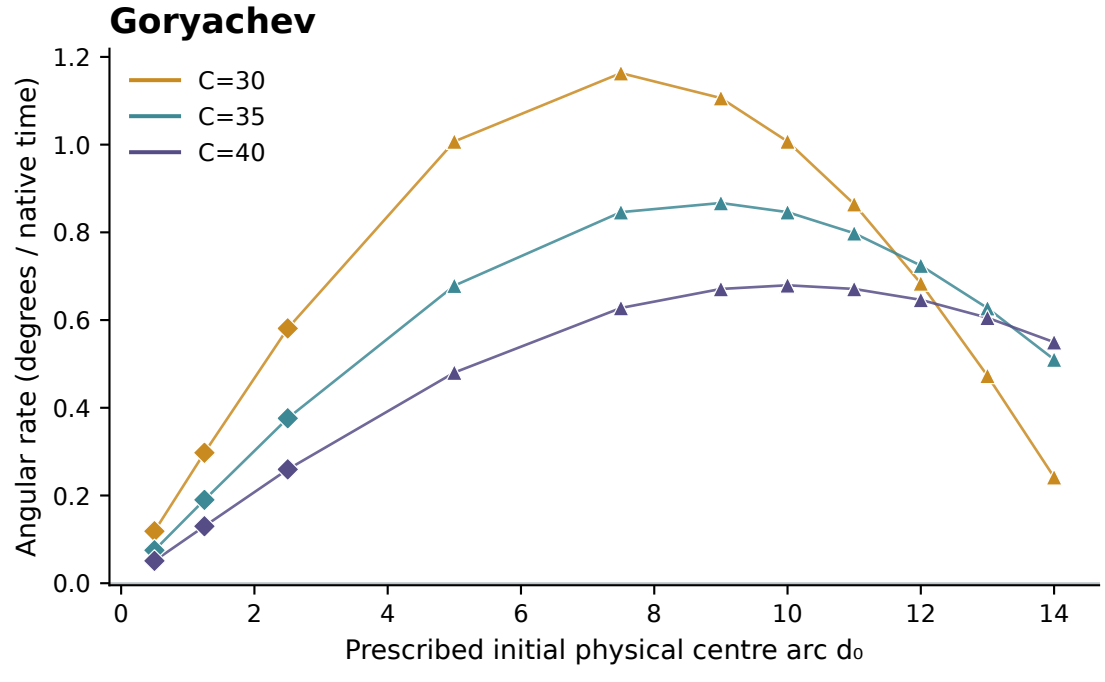
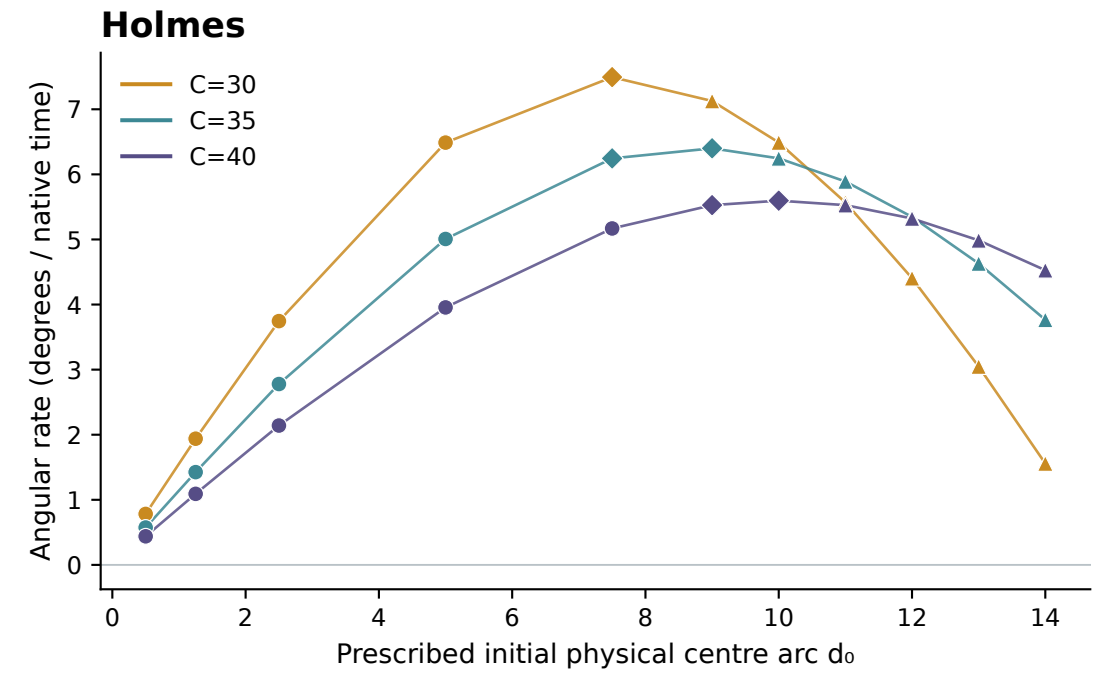
Global reorientation rate across physical cue distance and size

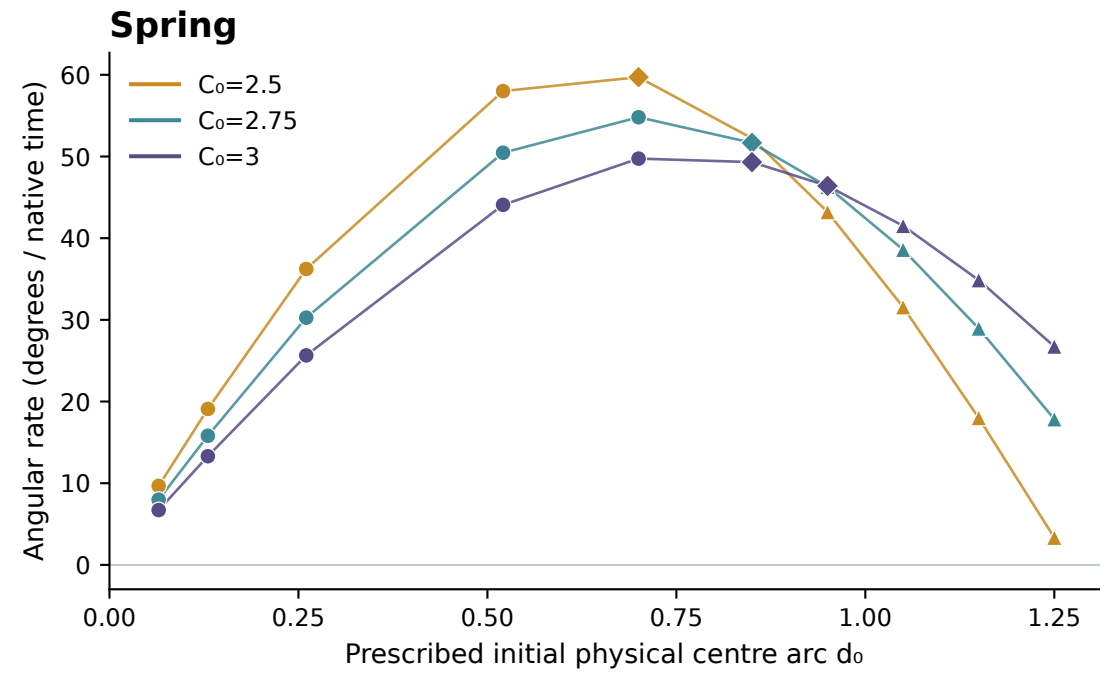
Exact native right-hand side at cue-on time t=0 · 129 prescribed placements · all initial footprint classes retained

● Initial full support inside ◆ Initial full support straddling ▲ Initial full support outside









Markers classify the complete initial cue support against the interpolated 10%-contrast edge; centre membership is separately reported.

All 129 rates are observed with R ≥ 0.1 at this instant. Lines guide the eye between tested positions; no continuous-distance fit is asserted.

The rate is activity-vector phase change, not local-peak speed. Initial projection, current moment magnitude and native organization all contribute.

Same native coefficients/supports/basals within each model. Holding d_0 fixed changes angular target and basal architecture; model clocks are uncalibrated.
