Spring · Cue-on response beyond the initial 10% edge

Narrow-range experiment · T = 1000 native units · 30/30 longest-cue histories available in this snapshot

Shared distances only: full supports clear all three initial 10%-contrast regions. Dotted heading lines mark actual cue targets.

Rate segments span their actual saved intervals, not instantaneous native-RHS values. Weak R < 0.1 creates gaps; no phase is unwrapped across them.

Time is linear 0–0.1, logarithmic thereafter. Rate y axes are linear near zero and logarithmic in magnitude beyond ±0.001; scales are not cross-model clocks.

A global angular rate includes projection and cancellation; it is not local-peak travel. Near-antipodal targets require the accompanying R and native profiles.
