One stationary-cue experiment · All 240 retained activity vectors

Arrows show actual final P = M_1/M_1(initial), after 13,000 cue-free units. Pale rightward guides mark the initial vector P = 1.

Each panel: four cue-centre angles × five tested durations. Columns are duration categories; native clocks are not calibrated across models.

Weak R < 0.1: an unoriented circle has radius proportional to R; its measured value is printed. □ failed field-tail gate; △ unavailable full-field tail.

* Cue support intersects the initial half-contrast core: all 125 overlap cases are retained. Physical support stays 3 for chemical models and 0.2 for Spring.

Arrows and circles use one global magnitude scale and equal data-coordinate scales. This is an endpoint-vector view, with no success threshold or minimum-duration claim.
